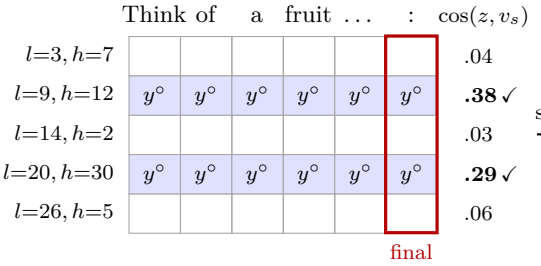
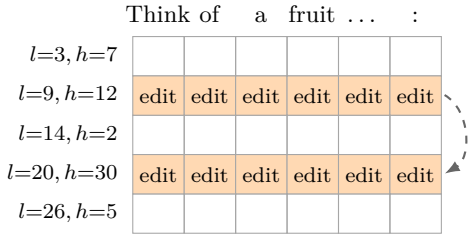
(a) Clean pass: choose sites, record y°



(b) Edited pass: same prompt



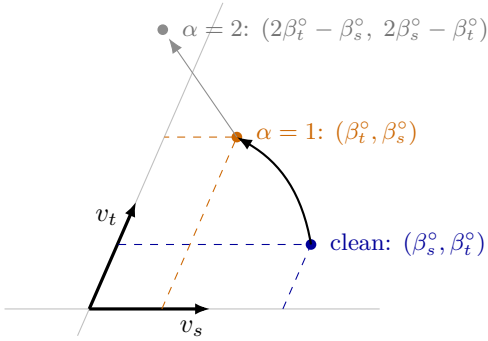
① Score every site at the final position; keep the top m ($m = 2$ here).

② Record the kept sites' outputs y° at every position, and their coordinates $\beta^\circ = V^+ y^\circ$.

③ Edit every position of each kept site:
$y \leftarrow y + V\big(\sigma_\alpha(\beta^\circ) - V^+ y\big)$

An earlier edit also changes y at later kept sites (dashed arrow); their two coordinates are still set to $\sigma_\alpha(\beta^\circ)$.

(c) The edit at one site and position, in the frame $V = [v_s\ v_t]$



Coordinates are the coefficients of y on v_s and v_t. The two directions need not be orthogonal, so the coefficients come from the pseudoinverse V^+. Only these two coordinates change; the part of y outside $\mathrm{span}\{v_s, v_t\}$ is left as it was.
